# Chapter 1: Introduction

## PSSA: THE PENNSYLVANIA SYSTEM OF SCHOOL ASSESSMENT

The purposes of the 2003 statewide assessment component of the Pennsylvania System of School Assessment, as specified in the new Chapter 4 Regulations, include providing:

- (1) an understanding of the students' and schools' achievement of the academic standards to students, parents, educators and community citizens,
- (2) a measure of the degree to which school programs enable students to attain the academic standards,
- (3) results to school districts, charter schools and AVTSs, Intermediate Units, Private Residential Rehabilitative Institutions, Approved Private Schools, Non-public and private schools for use in their strategic plans,
- (4) information to the general public and state policymakers regarding school achievement of the academic standards, and
- (5) aggregated results for all students as well as for Individualized Education Plan (IEP) and non-IEP students.

The broad purpose of the State Assessments is to provide information to teachers and schools to guide the improvement of curricula and instructional strategies to enable students to achieve the academic standards. The areas assessed in 2003 are mathematics and reading at grades 5, 8 and 11. *The Department strongly discourages the use of this testing information for "ranking" schools.*

## MATHEMATICS ASSESSMENT MEASURES

The PSSA mathematics assessment employs two types of test items: multiple-choice and open-ended. These provide differing types of information about mathematics achievement.

### *Multiple-Choice Items*

The majority of the mathematics items included in the PSSA are multiple-choice items. Multiple-choice items are also called "selected-response" since students choose their answers from the list provided. Such items are an efficient means of assessing a broad range of curriculum. They are relatively easy to develop and to administer in a group setting. They have proved particularly efficient in terms of amount of information gain per unit of testing time.

In the PSSA mathematics assessment, all multiple-choice items have only one correct response choice and the student is awarded one point for choosing it. For all items, students are provided with four response choices.

Multiple-choice items can be used to assess a variety of skill levels, from short-term recall of facts to problem solving. The great majority of the PSSA multiple-choice mathematics items require students to carry out some process to find their answers, rather than simply recalling

**The Pennsylvania System of School Assessment  
Mathematics and Reading 2003**

information from memory.

### ***Open-Ended Tasks***

Open-ended tasks require students to read a problem description and to write detailed solutions. Major components of such answers are clear presentations of the computations and explanations of the steps involved in the solution. The types of tasks utilized do not necessarily require computations. Students may also be asked to perform such tasks as drawing a graph, shading some portion of a figure or listing object combinations that meet specified criteria.

Open-ended tasks are especially useful for measuring students' problem-solving skills in mathematics. The tasks present real-life situations that require students to solve problems using math abilities learned in the classroom. Students must read the task carefully, identify the necessary information, devise a method of solution, perform the calculations, enter the solution directly in the booklet and explain the procedure to support the response. This provides insight into the students' mathematical knowledge, abilities and reasoning processes.

Open-ended tasks are scored manually on a five-point continuum of *correctness*. This continuum is defined by a *rubric*, which outlines the general requirements at each scale point. Scoring guidelines based upon the general rubric are developed to score individual items. The rubric approach to scoring has made it possible to include open-ended tasks in large-scale assessments, such as the PSSA. Readers who have received training in applying the rubric can score large numbers of student papers in a highly reliable way.

## **READING ASSESSMENT MEASURES**

The PSSA reading assessment employs two types of test items: multiple-choice and performance tasks. They are designed to measure students' comprehension of the information contained in the reading passages.

### ***Multiple-Choice Items***

Multiple-choice items measure such concepts as how well students comprehend the overall meaning of a passage or make basic inferences about it. At times, asking students to choose a preferred answer is the best way to determine whether they have gleaned certain important information from a story. Such information may include setting, central idea or main events and their chronology.

*Single-response multiple-choice* items are the familiar four response choices with one correct answer type. The student is awarded one score point for choosing the correct response. Distractors appeal to some kind of misinterpretation, predisposition, unsound reasoning or casual reading.

### ***Performance Tasks***

Performance tasks are designed to address comprehension of text in ways that multiple-choice items cannot. A written response allows students to reflect on what they have read, integrate

**The Pennsylvania System of School Assessment  
Mathematics and Reading 2003**

prior knowledge with text-based information, extend meaning and express their ideas.

These tasks are scored using the **Pennsylvania Reading Assessment Rubric**. This four-point scoring rubric describes a range of performance requirements at each level from minimal to very accomplished. Each task is carefully constructed to reflect the scoring rubric and to be text-dependent. Students may have the Pennsylvania Reading Assessment Rubric when responding to a performance task.

The rubric approach to scoring has made it possible to include performance tasks in large-scale reading assessments, such as the PSSA. The rubric approach also provides a highly reliable way to score a large number of student papers by readers who have received training in applying the rubric.

The rubric describes a hierarchy of responses containing each of the following three elements:

- *Understanding of the text* is demonstrated through a response that is both text-based and factual.
- *Level of comprehension of the text* is demonstrated through levels of thinking, from literal to personal, critical or evaluative responses.
- *Connection to the text* is demonstrated through responses that make connections to and go beyond the text.

## **MATRIX SAMPLING ASSESSMENT DESIGN**

The PSSA was originally designed as a complex matrix-sampling scheme, which was very efficient for measuring *school-level* performance but less efficient for providing *student-level* assessments and diagnostics. In this design, there are a *common* core of items to which all students respond and blocks of *matrix* items that vary by form. The matrix forms are *spiraled* within classrooms so that all forms are distributed uniformly within each classroom. This ensures that each matrix form is administered to an unbiased and sequentially random sample of students in each school. Since multiple forms are administered within each classroom, this allows the assessment to cover a wide range of topics at the classroom level.

Both the common and matrix sections of the PSSA use traditional multiple-choice items and open-ended performance tasks. Psychometrically, multiple-choice items are very useful and efficient tools for collecting information about a student's academic status. Open-ended performance tasks are less efficient in the sense that they generate fewer scoreable points in the same amount of testing time. They do, however, provide tasks that are more realistic and better sample the higher-level skills. The design of the PSSA attempts to achieve a reasonable balance between the two formats.

The design changes that began to take effect with the Spring 2000 administration shifted the focus of the measurement toward the student and away from the school. Beginning in 2000, student-level results were reported on the **Individual Student Report (ISR)** with diagnostic

**The Pennsylvania System of School Assessment  
Mathematics and Reading 2003**

results at the *academic content standard* level. All student-level results are based on the common items only and presented in the raw-score percent-correct metric only<sup>1</sup>. In order to accommodate this change in focus, the common section has been expanded to better reflect the curriculum. Unfortunately, to administer the tests in a reasonable length of time, enhancing the common sections came at the expense of the matrix sections.

The PSSA design is an attempt to have the best of both worlds:

- All student-level results are based on the common core of items that all students in a grade were administered. This ensures that all students are evaluated using the same set of items.
- School-level content area total score results are based on the mean of the student-level scaled scores. This ensures that the results used for school accountability directly reflect the student-level results.
- School-level results at the content standard (academic standards category) level, are based on the common items together with all items on the matrix forms. This insures that decisions regarding potential strengths and weaknesses better sample the entire curriculum.

Unfortunately, these dual objectives require some compromise:

- Many of the content standards are assessed with a minimal number of items. This is especially true at the student level. Consequently, scores reported for the academic standards categories in any metric would have large standard errors and are at risk of over-interpretation.

## **RECENT CHANGES**

A minimum scale score of 700 was implemented for all PSSA reading, mathematics and writing exams in 2002. This minimum is being applied for all the PSSA scales. It affects very few students, but some schools felt they were being penalized by the presence of some exceptionally low scoring special needs students who took the regular assessment. The change was made to reduce the impact of these students on the overall school score.

The following tables show how the two item types and the content standards are distributed across forms. Form W refers to the common sections and was the given to all students. Forms A through L for reading and mathematics are the matrix sections and each student took one of these forms in reading and one in mathematics.

---

<sup>1</sup> While the student-level scaled scores are not reported on the ISR, they are used for many of the underlying calculations.

## Chapter 2: Form Analysis and Item Calibration

### TEST FORM STATISTICS

The table below contains an overview of the form-level data. Test length (L), mean percentage of points received (P), typical test reliability (R) and typical standard error of measurement (SEM) are shown for each form by grade and content area. These statistics are based on the total test using both multiple-choice and open-ended tasks and both common and matrix sections for each form. The test lengths pertain to the data used for school-level estimates and not for student-level results.

The test reliability can be thought of as the correlation between scores if the students could be tested twice with the same instrument without the second testing being affected by the first. It is computed as the ratio of the variance associated with true scores divided by the total variance. The total variance contains a component due to the variance in true scores and a component due to the imperfections in the measurement process.

The *standard error of measurement* is another indicator of precision. If everyone being tested had the same *true score*<sup>1</sup>, there would still be some variation in observed scores due to imperfections in the measurement process. These may be random differences in attention during instruction or concentration during testing. Or perhaps differences could arise because of problems with the wording of the items or layout of the answer sheet. The standard error is the *standard deviation*<sup>2</sup> of the distribution of observed scores for students with identical true scores. Both reliability and the standard error increase with test length; although, it is not the sole determinant in either case. Comparing the information in Table 2-1 and Table 2-2 should give some insight into the complexities and tendencies of these statistics.

**Table 2-1: 2003 Summary Matrix Form Performances**

Grade	Mathematics				Reading			
	L	P	R	SEM	L	P	R	SEM
05	105	65	.93	4.9	90	66	.93	4.1
08	105	60	.94	5.5	120	68	.94	4.7
11	105	51	.94	5.2	132	66	.95	5.1

The Student-Level Scaled Scores were estimated using the common items only. This resulted in shorter test lengths and, therefore, slightly lower form reliabilities. The following table pertains to the common-item measures.

---

<sup>1</sup> True score is the score the person deserves and would actually receive if the measurement process were perfect.

<sup>2</sup> The standard deviation of a distribution is a measure of the dispersion of the observations. For the normal distribution about 16% of the observations are more than one standard deviation above the mean and the same percentage are more than one standard deviation below the mean. To illustrate, using the data in table 2.1, about 68% of students with true scores of 70 will have observed scores between 65 and 75.

**Table 2-2: 2003 Summary of Common Item Performances**

Grade	Mathematics				Reading			
	L	P	R	SEM	L	P	R	SEM
05	85	66	.92	4.4	60	66	.90	3.4
08	85	61	.93	4.9	80	68	.91	3.9
11	85	52	.92	4.7	88	67	.92	4.2

Appendix A presents detailed descriptions of the performance of each form by grade and content area.

The standard deviation shown in the table is the standard deviation of observed scores. Assuming normally distributed scores, one would expect about two-thirds of the observations to be within one standard deviation of the mean. An estimate of the standard deviation of the true scores can be computed as the  $\sqrt{(SD*SD) - (SE*SE)}$ . For grade 5 mathematics, this would be  $\sqrt{(15.5*15.5)-(4.4*4.4)} = 14.9$ .

The reliability can also be computed from these data. Again for grade 5 mathematics common,  $R = \frac{(15.5*15.5)-(4.4*4.4)}{(15.5*15.5)} = 0.92$ .

### TRADITIONAL ITEM STATISTICS

Although all items had been reviewed several times, a thorough item analysis was conducted to ensure that the items and forms performed as expected. With any psychometric model, an item analysis is a search for unexpected results. In general, *more able*<sup>3</sup> students are expected to pass easy items and *less able* students are expected to fail difficult items. If either of these situations does not occur, the item should be reviewed once more to determine the nature of the problem and the characteristics of the students affected.

The most familiar indices of item performance are *proportion correct* (p-value) and item reliability. Reliability for dichotomous items is typically represented by the *point biserial correlation* coefficient. This statistic will be positive if the total test mean score is higher for the students who respond correctly to the item than for the students who respond incorrectly. Hence, the correlation will be low if there is a *more able* way to fail the item or a *less able* way to pass it.

The p-value is a subtler indicator of item quality, but the value should be appropriate for the item. If there is a *more able* way to miss an item, the item will appear more difficult than the underlying problem. Conversely, if there is a *less able* way to pass the item, it may appear surprisingly easy.

Table 2-3 gives the mean p-value and point biserial correlation (PtBis) for the multiple-choice items in each grade and content area as a frame of reference of evaluating items. The p-value is

<sup>3</sup> Following the Rasch literature, *ability* is used in this discussion as a generic term for the construct that is being measured by the exam. *Competence, achievement, learning* and *status* are among the alternatives that are sometimes used, but are all subject to some degree of misinterpretation.

## Form Analysis and Item Calibration

the proportion of the students who responded correctly to an item. The point biserial correlation is the correlation between the student's score on the item (zero or one) and the score on the total test. This can be computed as the familiar Pearson product-moment correlation, but because the item score is a dichotomous variable, the formula can be written in a simpler form.

The point biserial correlation is also called the item reliability. The correlation will have a positive value when the mean score of the students answering correctly is higher than the mean score of the students answering incorrectly. This is a very reasonable requirement since it indicates that students who did well on the total test tended to do well on this item. The index will take its maximum theoretical value of 1.0 if *every* student who answered the item correctly scored better on the test than *any* student who answered incorrectly<sup>4</sup>.

In general, with the mean p-values in the low 0.56 to .70 range, the PSSA was quite challenging to most students. With the average point biserial correlations near 0.4, the overall item quality was quite good.

**Table 2-3: Typical Form Statistics by Grade and Content**

Grade	Mathematics		Reading	
	P-value	PtBis	P-value	PtBis
05	.70	.41	.68	.44
08	.63	.44	.69	.41
11	.56	.40	.68	.41

The item level analyses done for the PSSA also included the percent of students selecting each incorrect response (foil) and the correlation between selecting a response and total test score. This information (included in the appendices) is useful in helping item writers and editors understand the item's behavior. The percent selecting each response is an indicator of which foils are particularly attractive.

The correlations by response are a further refinement on this idea. They indicate which responses are attractive to high scoring students and which to low scoring students. The ideal pattern would be a *strong* positive correlation for the correct response and *strong* negative correlations for the incorrect responses. This pattern would indicate that the incorrect responses tend to attract students who tended to do less well on the total test. Consequently, one could conclude that the item is measuring the same construct as is the test as a whole.

## RASCH ITEM STATISTICS AND EQUATING

WINSTEPS<sup>®</sup> software implementing the Rasch model was used to obtain estimates of logit difficulties for both dichotomously- and polychotomously-scored items. The parameters estimated for polychotomous items are the *step difficulties* associated with the Masters Partial

---

<sup>4</sup> It is legitimate to view the point biserial correlations as standardized means. A positive value means students who chose that response had a higher mean score than the average student; a negative value means students who chose that response had a lower than average mean score.

## Form Analysis and Item Calibration

Credit model. This software is capable of handling all the item types currently in use with the PSSA.

Rather than percent correct, the Rasch model expresses item difficulty (and student ability) in units typically referred to as *logits*. In the simplest case, a logit is a transformed p-value with the average p-value becoming a logit of zero. In this form, logits resemble z-scores or standard normal deviates; a very difficult item might have a logit of +4 and a very easy item might have a logit of -4. They actually have no formal relationship to the normal distribution.

The logit metric has several mathematical advantages over p-values. It is an interval scale meaning two items with logits of zero and one are the same distance apart as items with logits of +3 and +4. Logits are not dependent on the ability level of the students. A specific form will have a mean logit of zero, whether the average p-value of the sample is 0.8 or 0.3.

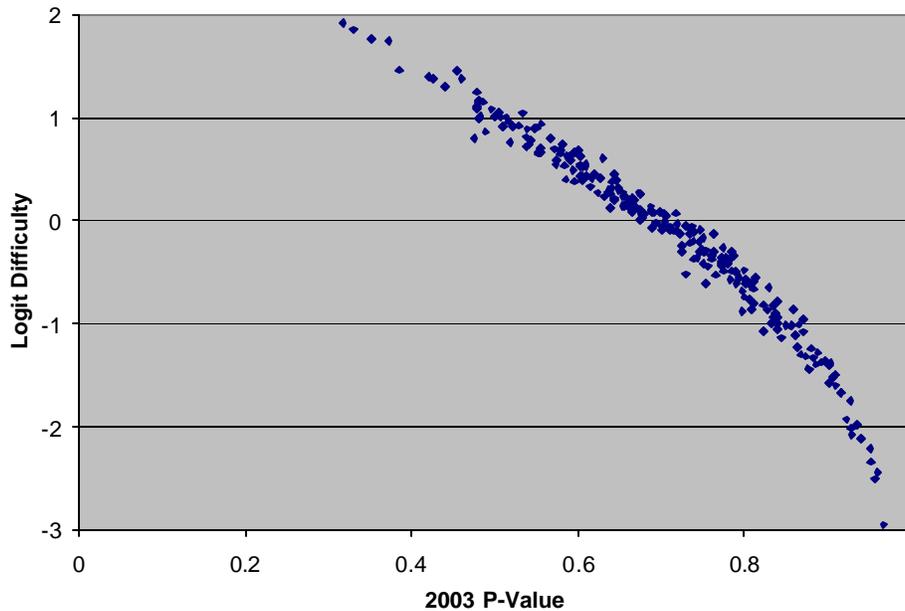

The standard Rasch calibration procedure arbitrarily sets the mean difficulty of the items on any form at zero. Any item with a p-value lower than the average item on the form receives a positive logit difficulty and any item with a p-value higher than the average receives a negative logit. Consequently, the logits for any calibration, whether it is a third grade reading test or a high school science test, relate to an arbitrary origin defined by the center of items on that form. The average third grade reading item will have a logit of zero; the average high school science item will have a logit of zero. This applies to logits for both item difficulties and student abilities.

There are any number of other arbitrary choices that could be made for centering the item difficulties. Rather than using all the items, the origin could be defined by a subset. For the PSSA, all test forms in a particular grade and content area share a common block of items. The items on all forms can then be easily adjusted to a single (but still arbitrary) origin by defining the origin as the mean of the **common** items. With this done, the origins for all twelve forms will be statistically equal. Items on forms A and L that are equally difficult should now have equal logit difficulties.

Since the test forms were spiraled within classrooms, there are some cross checks that are made to ensure the calibrations and links are reasonable. First, because of the spiraling, each form will be administered to a *statistically equivalent* sample of students. Any differences in performance observed among the groups should be due only to differences in form difficulty. After linking, the mean and standard deviation of the logit abilities should be statistically equal for each sample of students.

Second, because of the equivalent samples, the common items should have the same p-values regardless of which form and sample is being considered. Finally, for all items, both common and matrix, a plot of the relationship between the p-value and the logit should fall along a single, curved line. Figure 2-1 plots this relationship for the grade five mathematics assessment. The curve is nearly linear in the center, but curves towards asymptotes of zero on the left and one on the right.

**Figure 2-1: 2003 Grade 5 Mathematics P-Values versus Logit Difficulties**

In theory, with the Rasch model, linking the exam for the current year to the exam for previous years is just as straightforward as linking forms within year. However, the student samples can not be assumed equivalent across years and identical items can have different properties in different years because of changes in the item's context or changes in the student's experiences. Consequently, between-year linking is somewhat less certain than within-year linking.

The link between years must be from items that are used in both years in approximately the same context. The *same context* in this situation means the items are not altered in any way, they appear in about the same position in the booklet, and they are administered at about the same time of day. PDE provides a code for each item as part of the answer key file that indicates the item's appropriateness for linking. Codes between 1 and 6 represent the gradation of the item's suitability. A code of '1' means the item text is identical and its sequence number has not changed by more than 2 or 3. A code of '5' means the item has been significantly revised. A code of '6' indicates a completely new item.

For *within-year* linking, the procedure is to link forms through the common section. The result is a bank of items with comparable logit difficulties. For *between-year* linking, the procedure is to link the current year's bank to the previous years' banks. Theoretically, the process is identical to within-year.

- (1) Overlapping items are identified.
- (2) Adjusting the logit difficulties (of all items) in the current year's bank so that the mean logit difficulty for the overlapping items is equal to the mean logit difficulty for the same items in the previous year's bank.

## Form Analysis and Item Calibration

- (3) Assess the validity of the link by identifying any items that do not maintain their relative position across years.

Figure 2-1 above shows the 2003 logit item difficulties for grade five mathematics plotted against their respective p-values. Since the equating process forces the 2003 logit difficulties for the linking items to have the same mean logit difficulty as the 2002 logit difficulties for these same items, the 2003 logits will be displaced from their estimates obtained from an independent calibration. The size of the displacements should correspond to the approximate size of the standard errors for the items.

Plotting p-values against logit difficulties across year is not as reliable as it is within year. Using spiraled forms within year, a given p-value will translate to a given logit regardless of the form it is used on, within the limits of statistical precision. Within year, the p-value-to-logit plot should be a single curved line; between years, the plot could have separate lines for each year. The difference between the two lines is a reflection of the adjustment (positive or negative) that is required to equate the two item banks. This is the situation shown in Figure 2-2 (equated) and Figure 2-3 (unequated) with the curves using the square and the diamond plotting symbols.

**Figure 2-2: 2002 versus 2003 Logit Difficulties (Equated)**

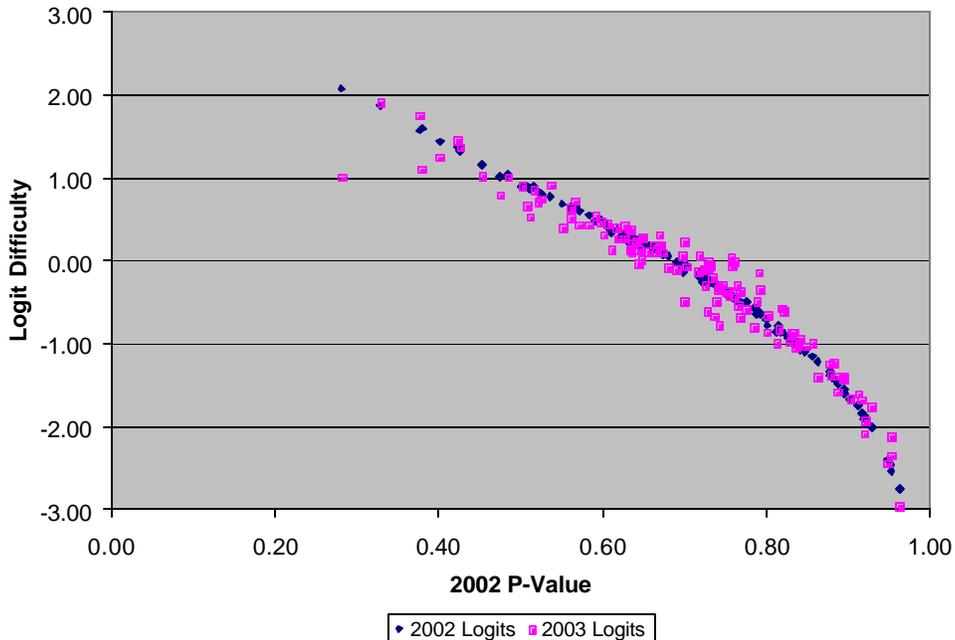

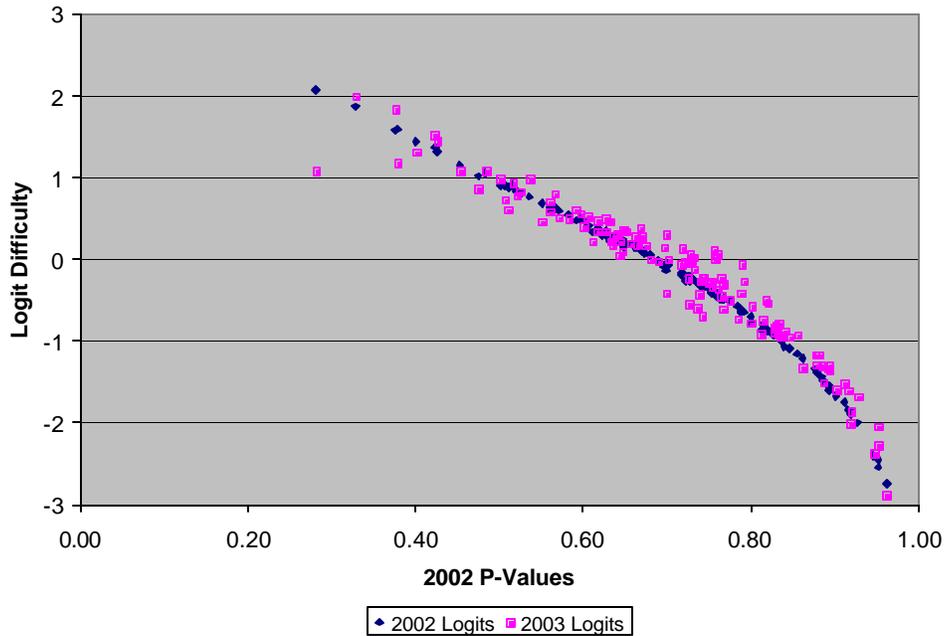

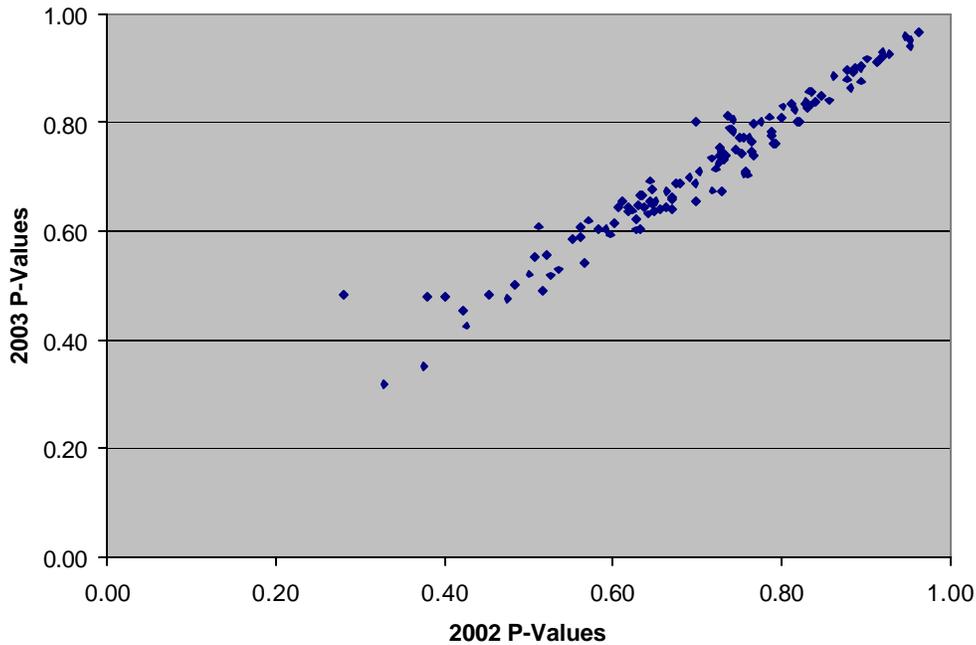

Figure 2-3: 2002 versus 2003 Logit Difficulties (Unequated)

The plot of the p-values for overlapping items from the two years can also be informative. If the p-values for the current year are systematically higher than for the same items last year, the scale scores should also show a systematic improvement after the two item banks have been properly linked. This is shown in Figure 2-4 with the diamond-plotting symbol.

**Figure 2-4: 2002 versus 2003 – Grade 5 Mathematics P-Values**

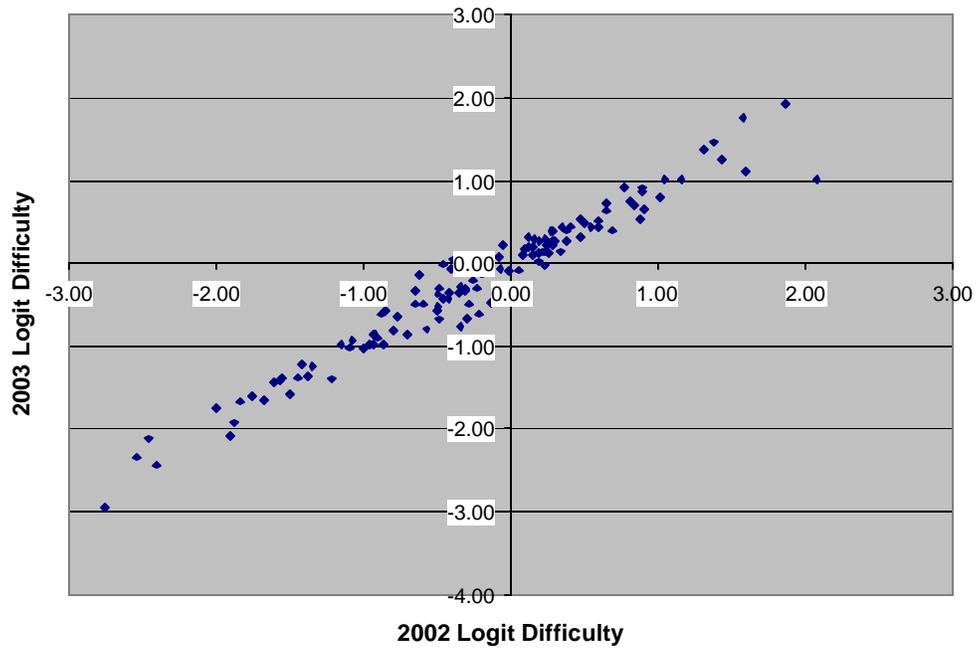

There are some checks on the reasonableness of the linking process that can be performed. Item calibration should be invariant across years, except for an arbitrary location constant. When the logit difficulties of the overlapping items for the current year are plotted against their logit difficulties for a previous year, the result should be a straight line, whose width reflects the standard errors of estimation for the item difficulties. Identifying any outliers and recomputing the adjustment based on an edited set of overlapping items should improve the link.

Figure 2-5 below uses the same data as Figure 2-2 and Figure 2-3, but focuses entirely on logit difficulties. It shows more clearly the relationship between 2002 logits and 2003 logits. There is a well-defined line with a few outliers. Since the plot shows the 2002 logits versus the *equated* 2003 logits, the line appears to pass through the origin.

Form Analysis and Item Calibration

Figure 2-5: 2002 versus 2003 – Grade 5 Mathematics Logit Difficulty

## Chapter 3: Linking and Equating

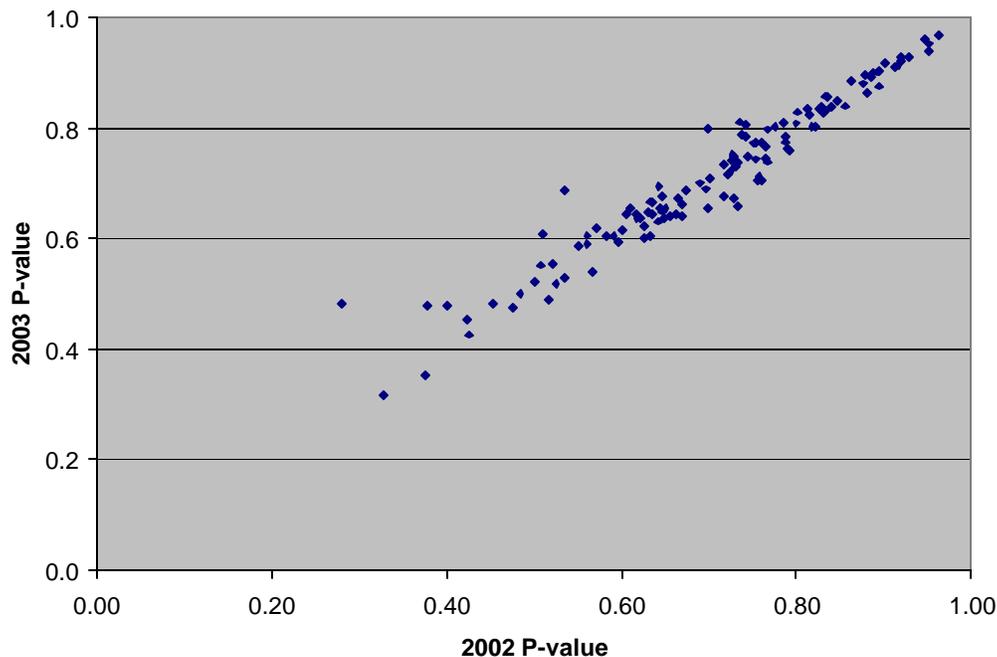

### GRADE 5: MATHEMATICS

The traditional item statistics, percent correct and point biserial correlations displayed typical and reasonable distributions for Grade 5 Mathematics. These statistics were computed for each test form, with an average item p-value of 0.70 and a median point biserial correlation of 0.42.

The percent correct scores ranged from about 0.32 to about 0.97 with 84% of the p-values falling between 0.5 and 0.9, while 74% of the point biserial correlations fell between .3 and .5. Only five point biserial correlations were less than 0.2 – all but one of which were matrix items. It might be useful to investigate the items with correlations near 0.6 as they may be exemplars for what items should be, or they might be tapping some extracurricular experience primarily available to the better math students.

Figure 3.1 and Figure 3.2 contain several pieces of information for the items that were used to link the 2003 exam to the 2002 exam. The diagonal line, rising from left to right in Figure 3.1, shows the item p-values in the two years. One would expect the relationship to form a straight line with slope one. The extent to which the line does not pass through the origin indicates a change in student performance. For Grade 5 mathematics, there was little change in the p-values from year-to-year.

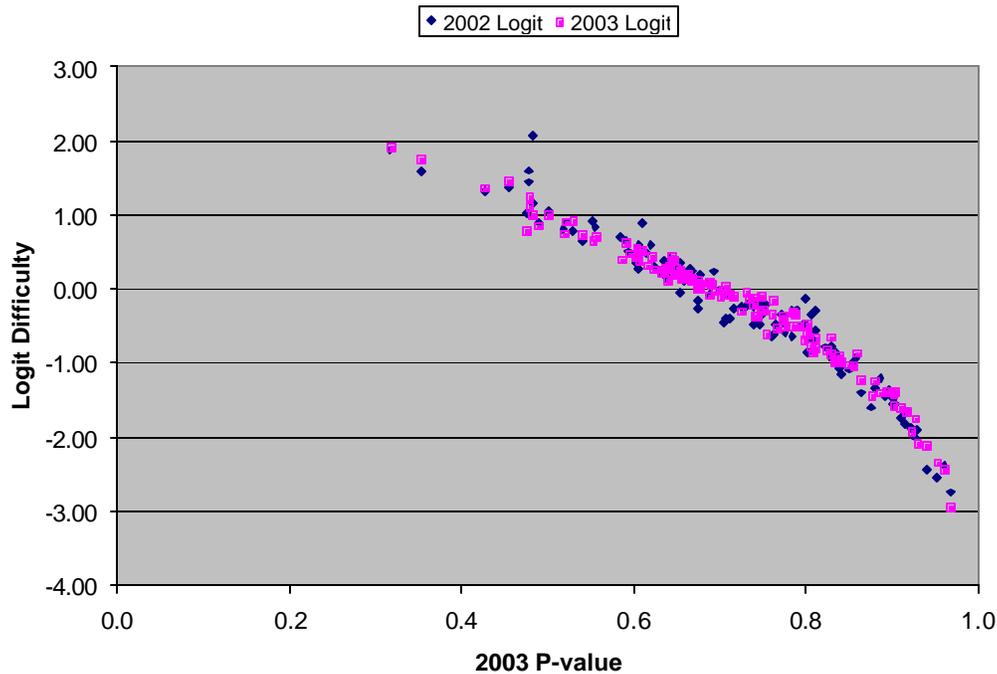

**Figure 3-1: Grade Five Mathematics P-Values**

## Linking and Equating

In Figure 3.2, the two lines sloping downward toward the right relate item logit difficulties for the two years to the 2003 p-values. They show the curvilinear relationship required by the model with low p-values being translated into high logit difficulties and high p-values into low difficulties. The smoothness of this line indicates good agreement among the twelve forms. Because the twelve forms were spiraled within classroom, the samples generated are randomly equivalent and one would expect the same p-value to translate into the same logit. This was the case with these data.

**Figure 3-2: Grade Five Mathematics Logit Difficulties versus P-Values**

### GRADE 5: READING

The traditional item statistics, percent correct and point biserial correlations displayed typical and reasonable distributions for Grade 5 Reading. These statistics were computed for each test form, with an average item p-value of 0.68 and a median point biserial correlation of 0.47.

The percent correct scores ranged from 0.19 to 0.94, but 84% of the p-values were greater than 0.5. Most of the item point biserial correlations were between 0.3 and 0.6 with only a few (16) items with correlations below 0.2. It might be useful to investigate the items with correlations near 0.6 as they may be exemplars for what items should be, or they might be tapping some extracurricular experience primarily available to the better students. There was a consistent pattern of the lowest reliabilities being associated with the lowest p-values. Most, but not all, items in this region are matrix items.

## Linking and Equating

**Figure 3-3: Grade Five Reading P-Values**

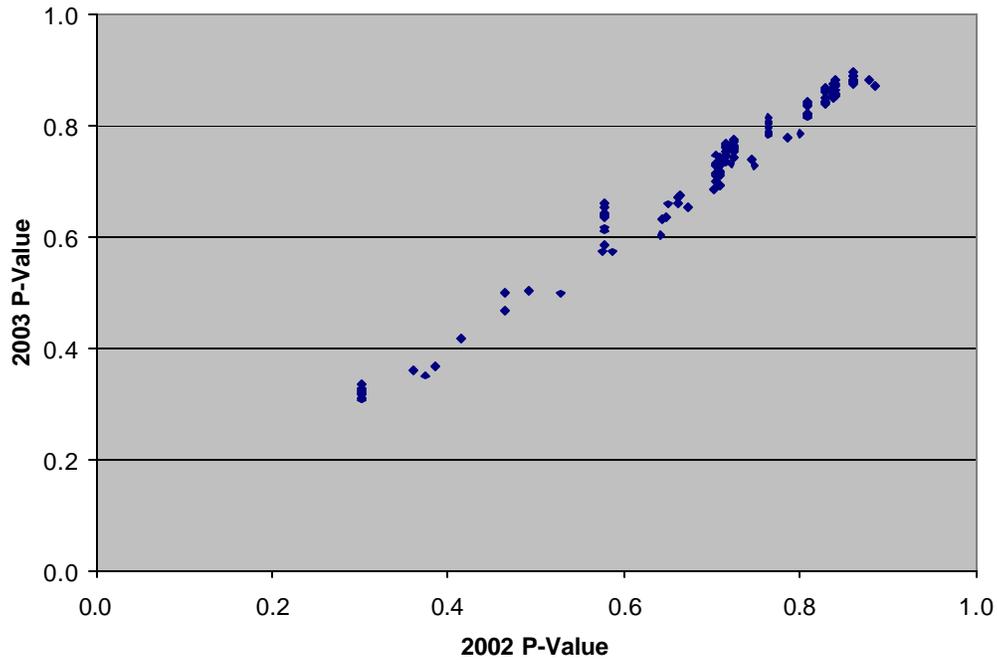

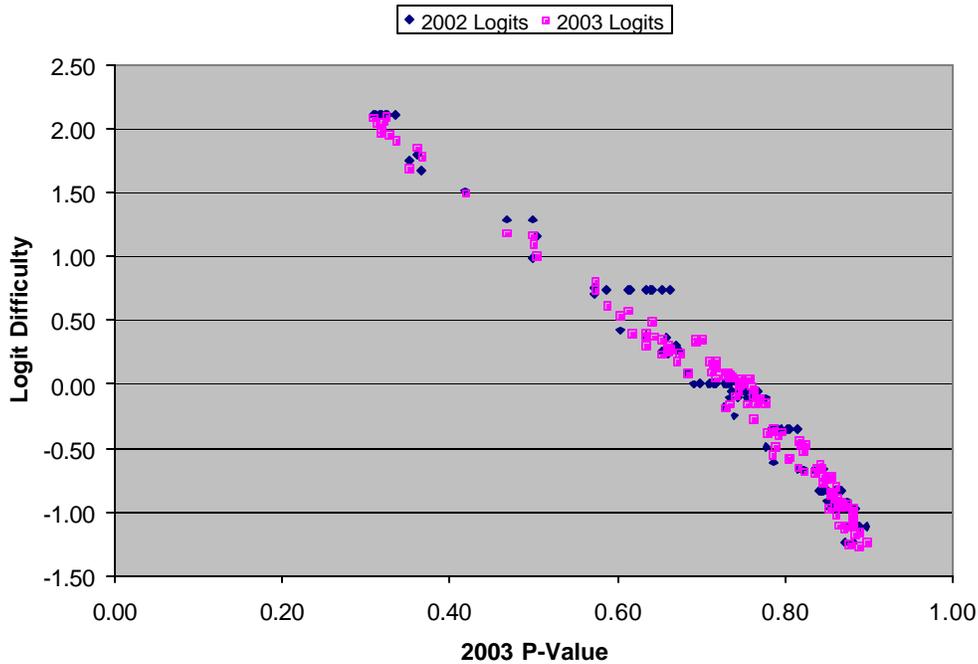

Figure 3.3 and Figure 3.4 contain several pieces of information for the items that were used to link the 2003 exam to the 2002 exam. The diagonal line, rising from left to right, shows the item p-values for the two years (the clusters of points reflect items which were used on multiple matrix forms). One would expect the relationship to form a straight line with slope one. The extent to which the line does not pass through the origin indicates a change in student performance. For Grade 5 reading, there was little change in the p-values from year to year.

## Linking and Equating

**Figure 3-4: Grade Five Reading Logit Difficulties versus P-Values**

The two lines sloping downward toward the right relate item logit difficulties for the two years to the 2003 p-values. They show the curvilinear relationship required by the model with low p-values being translated into high logit difficulties and high p-values into low difficulties. The smoothness of this line indicates good agreement among the twelve forms. Because the twelve forms were spiraled within classroom, the samples generated are randomly equivalent and one would expect the same p-value to translate into the same logit. This is the case with these data.

### **GRADES 8 AND 11**

Across-year linking analyses were performed for Grades 8 and 11 in the same manner as for Grade 5. The results were similar to Grade 5 in the amount of noise present in the links. These studies are documented in separate link analyses in files maintained by DRC.

## Chapter 4: Item Bias Review

Test item bias can present itself in a variety of ways in items: through the language, the format, the content, or the behaviors required. It can result from membership in a specific subpopulation or from factors correlated to the subpopulation. It can affect all members of the subpopulation, or it may affect only those in specific ranges of ability. How bias arises and how it presents itself clearly will affect how best to detect and correct it.

### LIMITATIONS OF STATISTICAL DETECTION

No statistical procedure should be used as a substitute for rigorous, hands-on reviews by content and bias specialists. The statistical results can help to organize the review so the effort is concentrated on the most problematic cases; however, no items should be automatically rejected simply because some statistical method flagged them or accepted because they were not flagged.

Statistical detection of item bias is at best an inexact science. There has been a variety of methods proposed for detecting bias, but no one statistic to date can be considered either necessary or sufficient. Different methods are more or less successful depending on the situation and circumstances. No analysis can guarantee that a test is free of bias and almost any thoughtful analysis will uncover the most flagrant problems.

A fundamental shortcoming of all of the statistical methods is that all are intrinsic to the test being evaluated. If a test, overall, is unbiased but with one or two biased items, most methods will locate the problems. If, however, the test itself is biased against one or more subpopulations, a statistical analysis of the items will not be able to separate bias effects from true differences in achievement.

### MANTEL-HAENSZEL PROCEDURE FOR DIFFERENTIAL ITEM FUNCTIONING

The *Mantel-Haenszel* procedure for detecting differential item functioning is the most commonly used technique in educational testing. It does not depend on the application or the fit of any specific measurement model. It does have some philosophical overlap with the Rasch model since it uses total score to organize the analysis.

*Differential item functioning* is present when examinees of equal ability do not have the same chance of passing the item. If this inequity is associated with gender or ethnic groups, the item could be described as biased. The Mantel-Haenszel procedure looks for items that meet this idea of differential functioning.

The procedure as implemented by DRC contrasts a focal group with a reference group. While it makes no practical difference in the analysis which group is defined as the focal group, the protected class or the group most apt to be disadvantaged by a biased measurement is typically defined as the focal group. The Mantel-Haenszel statistic (MH) for each item is computed from a two-by-two-by-eight contingency table. It has two groups (focal and reference), two outcomes (right or wrong) and eight ability groupings. The ability groups are defined by the octiles of the score distribution for the total examinee populations.

## Item Bias Review

The basic MH statistic is a single degree of freedom chi-square that compares the observed number in each cell to the expected number. The expected counts are computed to ensure that the analysis is not confounded with differences in the achievement level of the two groups. For constructed response items, a comparable statistic is computed based on the standardized mean difference computed as the differences in mean scores for the focal and reference groups, if both groups had the same score distribution.

To assist the review committees in interpreting the analyses, the items are assigned a severity code based on the magnitude of the MH statistic. Items classified as A+ or A- have no statistical indication of differential item functioning. Items classified as B+ or B- have some indication and may not require revision. Items classified as C+ or C- have strong evidence of a problem and should be reviewed and revised if they are to be used again. The plus sign indicates the item favors the focal group and a minus sign indicates the item disfavors the focal group.

The complete results of the DIF analysis are listed in appendices Q through V. The results include the MH statistics and codes for all matrix items as well as displays such as the following for all items given the C classification. This display identifies the item by form and sequence number and provides all the descriptive statistics. For each score grouping, the display gives the number in each group and the percentage of the group who answered the item correctly. For example, for the item shown, there were 901 students from the focal group in the lowest group and 45% of them answered the item correctly.

Selected	Response	Form	Seq	Ref	Focal	d.f.	ChiSq	M.S.	OddsRatio	Effect	Code
	X	135	2	1	8	447.43	55.93	2.13	-1.8	C-	
0	1	2	3	4	5	6	7	8	9	0	
FOCAL										-REFERENCE-	
							*+	1.00	928	0.99	761
							-*	0.98	962	0.99	870
							-*	0.96	871	0.98	814
							*	0.96	892	0.97	920
							--*	0.93	922	0.95	882
							---*	0.86	881	0.92	923
							-----*	0.75	881	0.88	896
							-----*	0.45	901	0.65	787
0	1	2	3	4	5	6	7	8	9	0	Right Total
											Right Total

The following tables provide counts of the number of items from each grade and content area that were assigned to each severity code. Overall, there were relatively few items that showed strong evidence of differential item functioning.

## Chapter 5: Student and School Level Scaling

Prior to 2000 testing, when the PSSA design was more heavily matrix sampling, estimating school-level scaled scores presented some statistical and psychometric challenges. For example, the statistically efficient method to compute the school-level scaled score often gave an answer different from what would be obtained by averaging student ability estimates. To avoid this source of misunderstanding, the school-level scores were forced to equal the average of the appropriate students. The matrix sampling component of the design, together with items from the common section, was used at the academic standard category level to estimate relative strengths and weaknesses for the school.

Beginning in 2000, with the new reporting design, content area total scores for students and for schools were based exclusively on the common sections. Thus, greater emphasis was placed on the common sections to possess optimal balance at the content standard level and yield reliable estimates of student-level abilities, as indicated by the standard errors. It was then possible to aggregate all scaled scores to the school, district and state levels without resorting to any complex algorithms, making the results simpler to explain and interpret.

Because the original design of the PSSA was intended to produce school-level estimates only, the reporting metric was defined at the school level. For the base year, the mean of all schools in the norming sample was set at 1300 and the standard deviation at 100. The distribution to which these apply is the content area scaled score with all schools weighted equally. Consequently, the expectation in 2000 was for state-level means near 1300 and standard deviations near 100. The state mean of student level scaled scores is, in general, somewhat different. This difference occurs because the mean of the school-level scores counts schools equally, regardless of size, while the mean of the student-level scores counts students equally.

For the eleventh grade, the PSSA also requires computing school-level results separately for vocational/technical students and non-vocational/technical students. Because student-level scaled scores are available for every student, this step simply requires a separate aggregation of student scores.

A minimum scale score of 700 was implemented for all PSSA reading, mathematics, and writing exams beginning in 2002. This minimum is applied to all the PSSA scales.

Although it affects very few students, some schools felt they were being penalized by the presence of extremely low scoring special needs students who took the regular assessment. The change was made to reduce the impact of these students on the overall school score.

One would not expect large changes from year to year at the state level. Any change would typically be in the same direction and proportional to changes in the p-values for the linking items. One would also expect schools that put more resources into effecting changes to show relatively more progress than those that do not. This type of information is not available in a systematic way and any evaluation of this type would depend on anecdotal information.

Table 5.1 gives the transformations that were used to convert 2003 logits (X) into the scaled scores. These translation constants included the adjustments to equate 2003 to prior years as

## Student and School Level Scaling

well as the rescaling needed to convert to the appropriate metric. These transformations are used for all scaled score calculations.

**Table 5-1: Transformation to Scaled Scores**

<b>Grade</b>	<b>Mathematics</b>	<b>Reading</b>
<b>Five</b>	$190X + 1134$	$199X + 1095$
<b>Eight</b>	$178X + 1182$	$235X + 1114$
<b>Eleven</b>	$206X + 1203$	$245X + 1115$

### COMMON ITEMS AND MATRIX SAMPLED ITEMS

With the new design for the 2000 PSSA, student-level scores are based on the common items only. This ensures that any decision made about students will be done in the most equitable manner. School-level scaled scores for the content areas are based on the mean of the student-level scaled scores. This ensures that the scaled scores used for school accountability directly reflect the student-level results. It is a simple matter to aggregate up to the school, district, and state levels.

For the purpose of providing school-level results at the content standard (academic standards category) level, all items on all matrix forms plus the common items are utilized. This insures that decisions about potential strengths and weaknesses are based on the widest possible sampling of the curriculum.

### SCALED SCORES FOR CONTENT STANDARDS

Beginning in 2003, school-level scaled scores are no longer reported for the academic content standards (academic standards categories). Instead, school results are presented as the percent of total points achieved as compared to district and state level results.

## Chapter 6: Interpreting Scaled Scores and Performance Levels

A *Scaled Score*, in the simplest sense, is a transformed number correct score<sup>1</sup>. When all students take the same items, as in the common sections of the PSSA, the more points the student earns, the higher the scaled score received will be. The value of switching to the more abstract scaled score metric is to produce a more general result.

A raw score of, say, 30 is almost meaningless unless the reader is also told how many points were possible. The same score has quite different meanings if it is based on a thirty-item test or on a sixty-item test. *Number correct scores are transformed to percent correct scores to remove the effect of test length.* In the same way, a score based on sixty difficult items is quite different from the same score based on sixty easy items. *Number correct scores are transformed to scaled scores to remove the effects of test length and item difficulty.*

On the surface, a scaled score of, say, 1300 does not appear to have any more meaning than a raw score of 30. A temperature of 37 degrees does not provide useful information unless the scale is anchored to some known points. Useful anchors might be the freezing point of water or perhaps the normal body temperature for humans.<sup>2</sup> To be meaningful, the new metric must be related to known objects and situations, in other words, to some sort of *measurement standard*.

### SCHOOL-LEVEL SCALED SCORES

The PSSA scaled score metric has been anchored to the *mean school level scaled score* for a base year and that point has been arbitrarily labeled 1300. The point on the scale that is one standard deviation above the mean was labeled 1400. These labels are completely arbitrary; they could have been called zero and one or any other ordered pair without affecting any of the relationships among schools, years, students or items. It would simply be changing the labels on the axis of a graph without moving any of the points.

The 1300-metric was chosen so that negative or fractional scaled scores are not needed and so that the PSSA scaled scores are not easily confused with the results from any other testing program. Like the temperature scales of Fahrenheit and Celsius, the new scale will acquire meaning only with experience.

A scaled score of 1300, or any other value, should have the same absolute meaning in the current year as it had in previous years, when properly equated across years. A school with a scaled score above 1300 performed better than did the average school in the base year.

More importantly, an increase in the scaled score from last year to the current year means the students' performance has improved; it does not say anything about whether the exam is easier or harder. To make these interpretations requires no information about the length or the difficulty of the test in either year, although all of those are essential information for deriving the scaled scores.

---

<sup>1</sup> This is done in two steps. First, there is a nonlinear transformation that converts number correct scores to logits and then a linear transformation to convert logits to scaled scores.

<sup>2</sup> Most adults have enough experience with temperature scales that being told the temperature is on the Fahrenheit scale or on the Celsius scale is enough information to render the measure useful.

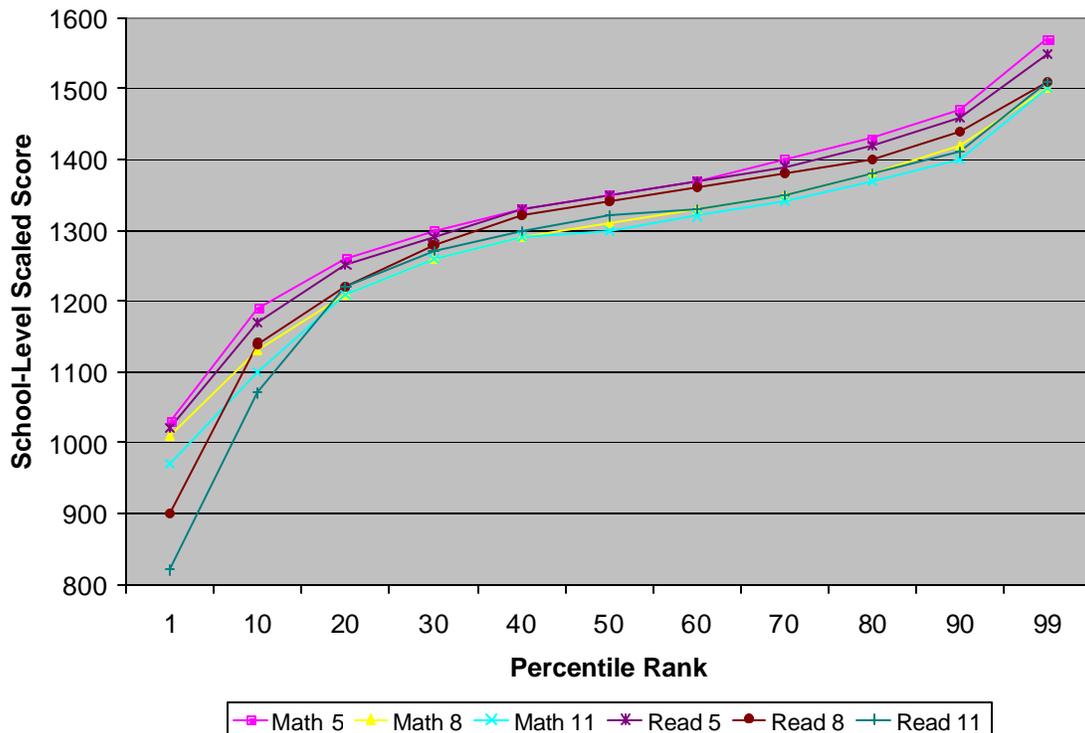

## Interpreting Scaled Scores and Performance Levels

In the base year, the standard deviation of the school-level scaled scores was set to a value of 100. If school scores are approximately normally distributed, a scaled score of 1400, one standard deviation above the base year mean, means the school did better than about 5/6 of the schools in the base year. About two thirds of the schools will have scaled scores between 1200 and 1400. Conversely, about 16% of the schools will be below 1200. Scaled scores of 1000 and 1600 are three standard deviations from the mean and so are extreme scores.

The best guide for giving meaning to the scaled scores is experience. Knowing the typical school had a scaled score of 1300 in the base year provides a beginning for understanding the metric. Most importantly, comparing a school's score to its scores in previous years should be a good indicator of progress.

Another approach to understanding the meaning of the scores is the percentile rank as shown in Figure 6.1 below. This plot converts the school level scaled score into a percentile rank that describes the distribution of scores for all schools in the norming sample for the current year. This chart applies only to school-level scaled scores computed from the common and matrix sections of the exam and can not be used for student level scores. A complete table of school-level percentile ranks is given in Appendix W.

**Figure 6-1: 2003 School-Level Percentile Rank**

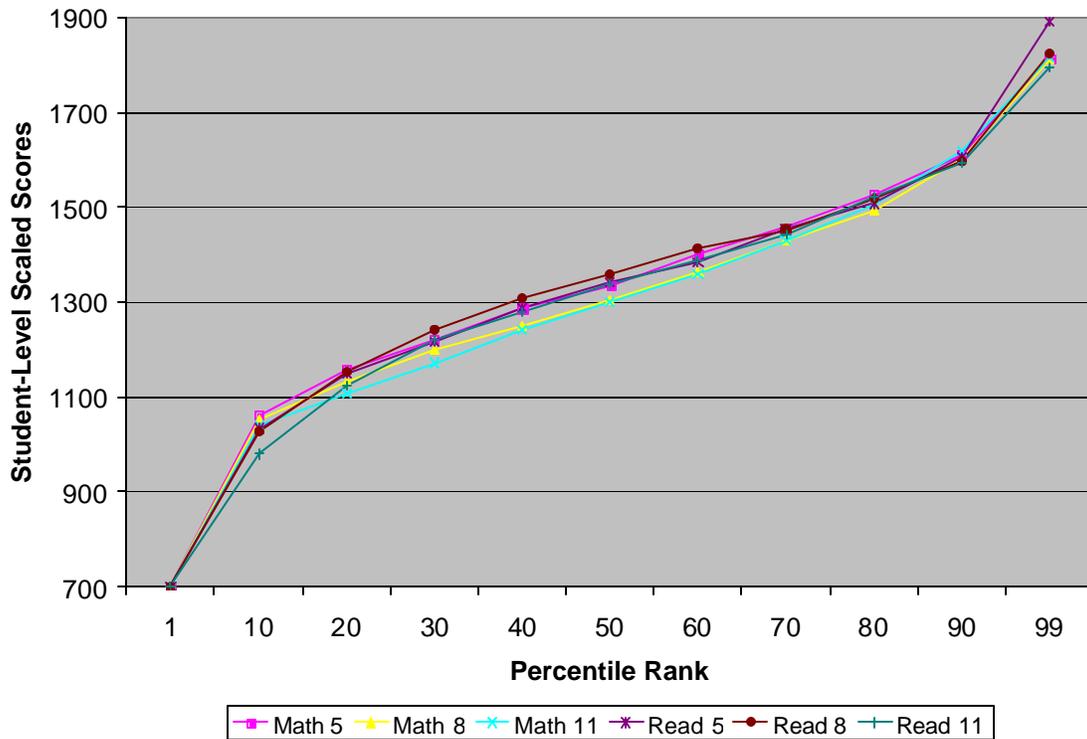

## STUDENT-LEVEL SCALED SCORES

This discussion has been focused on the meaning of the metric at the school level. For the students, the mean scaled score will also be close to 1300, but the standard deviation will be about twice as large.

In interpreting a student-level scaled score, the student's measure can be compared to the mean of the school or to other students in the state. Another approach is to examine the percentile rank of a student's score. Figure 6.2 plots the student-level scaled scores against a percentile rank that describes the distribution of scores for all students in the norming sample for the current year. This table applies only to student-level scaled scores computed from the common sections of the exam and cannot be used for school-level scores.

A complete percentile rank table that includes conversions for points received as well as scaled scores is included in Appendix X.

**Figure 6-2: 2003 Student-Level Percentile Rank**

## PSSA PERFORMANCE LEVELS FOR MATHEMATICS AND READING

- Advanced:** Superior academic performance indicating an in-depth understanding and exemplary display of the skills included in Pennsylvania's Academic Standards;

## Interpreting Scaled Scores and Performance Levels

- **Proficient:** Satisfactory academic performance indicating a solid understanding and adequate display of the skills included in Pennsylvania’s Academic Standards;
- **Basic:** Marginal academic performance, work approaching, but not yet reaching, satisfactory performance. Performance indicates a partial understanding and limited display of the skills included in Pennsylvania’s Academic Standards. The student may need additional instructional opportunities and/or increased student academic commitment to achieve the Proficient Level;
- **Below Basic:** Inadequate academic performance that indicates little understanding and minimal display of the skills included in the Pennsylvania Academic Content Standards. There is a major need for additional instructional opportunities and/or increased student academic commitment to achieve the Proficient Level.

The scores that correspond with each performance level are located in Table 6.5.

Performance Levels for Each Grade and Subject		
	Mathematics	Reading
<b>Grade 5</b>		
Advanced	1460 and above	1480 and above
Proficient	1300 -- 1459	1300 - 1479
Basic	1170 -- 1299	1160 - 1299
Below Basic	1169 and below	1159 and below
<b>Grade 8</b>		
Advanced	1510 and above	1490 and above
Proficient	1300 -- 1509	1280 -- 1489
Basic	1180 -- 1299	1130 -- 1279
Below Basic	1179 and below	1129 and below
<b>Grade 11</b>		
Advanced	1490 and above	1520 and above
Proficient	1310 -- 1489	1290 -- 1519
Basic	1180 -- 1309	1140 -- 1289
Below Basic	1179 and below	1139 and below

**Table 6.5: Scores Associated With Performance Levels**

## PSSA RELIABILITY OF PERFORMANCE LEVELS

### *Indicators of Consistency*

Criterion-referenced tests are often used to place the examinees into two or more performance classifications. It is then useful to have some indication of how consistent such classifications are. Livingston (1972) argued that a measure of consistency should be a function of the reliability of the test increases and the distance between the performance standard and the mean

## Interpreting Scaled Scores and Performance Levels

of the distribution. Livingston's coefficient, which was formulated from the perspective of True Score Theory, is defined by:

$$1. \quad \kappa^2(X,T) = [ \sigma^2_T + (\mu_T - C)^2 ] / [ \sigma^2_X + (\mu_X - C)^2 ]$$

If the expressions in parenthesis are zero, equation 1 is the ratio of the true score variance to the observed score variance, which is a standard definition of reliability. The numerator is increased by adding the squared difference between the true score mean and the cut score. The denominator is increased by the difference between the observed score mean and the cut score.

The coefficient is normally computed, from data, by setting the true score mean equal to the observed score mean and multiplying the observed score variance by the KR-20 reliability coefficient to obtain a value for the true score variance.

$$2. \quad \kappa^2(X,T) = [ r \sigma^2_X + (\mu_X - C)^2 ] / [ \sigma^2_X + (\mu_X - C)^2 ]$$

If  $(\mu_X - C)$  is zero, expression 2 will return the value of the KR-20; if it is non-zero, the value will be larger than the KR-20.

For the 2003 PSSA, values for the Livingston Coefficient of Consistency are given in the table below.

**Table 6-1: 2003 Reliability of Performance Levels for the PSSA**

<b>GRADE</b>	<b>CONTENT</b>	<b>BASIC</b>	<b>PROFICIENT</b>	<b>ADVANCED</b>
<b>Five</b>	<b>Reading</b>	.93	.90	.94
